Instructions:

- This is a sample competency test. The questions are mainly extracted from lecture slides.
- It will be good to attempt the test under exam condition: Limited time, No books or notes, no computer, no breaks, etc.
- For the details of competency test, follow the guidelines provided during the lectures.

Answer all the questions. You are not allowed to import any libraries or module for any of the solution.

1. Write a function `ssq(lst)` which returns the sum of squares of the input list. You can assume the input list to contain numeric data only. For example, `ssq([1,2,3,4])` returns `30`.

2. Write a function `grade(marks)` which returns the grade for the input marks. The distribution of grades in provided in the table below. For example `grade(88)` returns `'HD'`.

3. Write a function `stocks(filename)` which extracts all the data from an input CSV file `filename` and returns sum of the numeric data extracted from the file. You can assume that the file contains only numeric data separated by comma which is distributed over many lines (CSV file). For example, `stocks("stock.csv")` returns `105`
   The file stock.csv contains following lines

   ```
   1,2,3,4,5
   6,7,8,9,10
   11,12,13,14
   ```

4. Write a function `inputmarks(subject)` which asks the user to enter final mark for the input `subject` and returns a valid numeric number in the range between 0 and 100. The function keeps on repeatedly asking for the valid input till valid entry is made. You can assume that user will always be entering numeric value.
